(54) Title: SOLAR THERMAL ROOFING

(57) Abstract: A roof or wall face comprises a plurality of battens (216a, 216b) etc space apart to define a plurality of transverse courses each including a space (226). The roof has an outer layer of tiles (218a, 218b, 218c) etc transparent to solar radiation, and an inner layer of metal or other strips (214a, 214b, 214c) etc absorbent to solar radiation. A pipe (228) extends through each space (226) and is thermally connected to each of the absorbent strips (214a) etc. The pipe (228) forms a circulatory duct for a solar heating system. Solar radiation incident on the roof passes through the transparent tiles (218a) etc to be absorbed by the strips (214a) etc, whereby a heat transfer fluid in the pipe (228) is heated for the system. Air held in each space (226) provides an insulative blanket. The strips (214a) etc are formed to provide ventilation and a run-off for moisture.

WO 02/31415 A1

Solar Thermal Roofing

This invention concerns solar thermal roofing, which is to say roofing which collects heat from sunlight for space or water heating.

5 It is well known that solar energy may be used to provide hot water, and this is common in tropical and sub-tropical countries. In higher latitudes the gain is less but still beneficial. In Britain, for instance, solar energy can provide domestic hot water for an average family through the summer months and a useful top-up (by pre-heating the water supply) through the
10 rest of the year. Over the course of a year a south-facing roof in Britain receives about 1000 kWh/m², which is clearly an important potential source of energy.

 Typically the solar energy is captured by means of a so-called flat plate collector which is often mounted upon a roof. The collector comprises
15 a closed box with a transparent cover and, inside the box, an absorber plate coloured black or otherwise treated to absorb incident radiation. Water passed through pipes within the box is heated. The amount of energy captured depends upon the size of the collector, which is naturally limited by handling and aesthetic considerations, particularly when the
20 collector is roof-mounted. Also, importantly, the effectiveness of the collector depends upon limiting heat loss, and as well as being thermally insulated the box is conventionally closed to prevent convective heat loss. Thus in use still air provides a blanketing effect so that heat builds up in the box.

25 It is previously known to cover a roof with photovoltaic tiles to generate electricity, but it will be appreciated that these are relatively easy

-2-

to connect together. For a thermal system, however, conventional flat plate collectors, if reduced to the size of a typical roof tile, would entail unacceptable time and cost in interconnection. Accordingly various previous proposals have been made to adapt roofing tiles to deliver solar heating.

Offenlegungsschrift DE 3934719 discloses an arrangement in which aluminium tiles are shaped to hook over pipes of a solar heating system, which pipes thereby serve as tiling battens. The tiles are anodised and have a matt black outer face so as to absorb incident solar radiation and pass heat on to water circulating through the pipes. This system lacks any insulative covering for the tiles, which would thereby suffer considerable heat loss from convection, and even more so when subject to precipitation and afterwards due to evaporation.

Offenlegungsschrift DE 3218013 has a tiling batten which is itself made of thermally conductive metal and embraces a pipe for a solar heating system. However it is proposed that conventional roofing tiles be hung from these battens, which restricts the solar gain because conventional tiles are not transparent to solar radiation. A further reduction of effectiveness stems from the fact that the battens cover only a comparatively small part of the roof area which could be used for collecting solar heat.

United States Patent 4,202,319 discloses roofing tiles in the form of reduced-size flat plate collectors. Each of these tiles has an inlet and an outlet connected to channels in a batten, thus providing a circulatory route for fluid of a solar heating system. Those skilled in the science will appreciate that the need to ensure a fluid-tight connection between each

-3-

tile and its supporting batten places great demands on both the accuracy of manufacture and the skill of the roofer. This implies high cost, which is raised further by coils or a similar heat collecting structure within each tile.

5 A much simpler approach is proposed in Japanese Patent No. 4 343 963 whereby heat exchange pipes are laid within grooves formed in fibreboard roofing sheets which are then covered with transparent tiles. However with the arrangement disclosed there is no provision for the desirable blanket of still air.

10 United States Patent 4,364,374 discloses a tile-like panel with a plurality of spaces for air. However this air circulates (for the purpose of heat transfer) rather than acting as a blanket. Further, the panel is designed and arranged in such a way that connection to a solar heating system is provided by means of a pipe extending through one of the spaces which, when the panel is connected to others on a pitched roof, makes an open
15 passage for air from the base to the summit of the roof. This necessarily entails substantial convective heat loss.

United States Patent 4,083,360 discloses an arrangement in which one or more flat plate collectors are disposed between rafters of the roof, beneath an area of radiation-transmitting tiles. The tiles may be formed, in
20 the manner of double glazing, to provide heat insulation, and it is stated that the collectors may extend throughout the slope of a roof.

United Kingdom Patent 2 070 232 discloses a roof structure for collecting thermal energy in which air passes through ventilation elements under tiles of the roof. The tiles are conventional, so they are not
25 transmissive of solar radiation as in a normal collector, and the system provides for an air flow rather than a blanket of substantially still air.

-4-

It is an object of the present invention to provide solar thermal roofing (or walling, since the invention is equally applicable to vertical surfaces) which has the desirable heat insulation of flat plate collectors but without the additional cost and complication thereof.

5 Thus according to the present invention there is provided a roof or wall face comprising a plurality of battens spaced apart to define a plurality of transverse courses, a plurality of tiles supported by the battens in the courses defined thereby to provide an outer layer of said face, which tiles are transparent to solar radiation, a plurality of strips arranged one for each
10 course to form an inner layer substantially coextensive with the outer layer, which strips are absorbent to solar radiation, and a duct for a fluid heat transfer medium of a solar heating system extending adjacent the strips so that in use the fluid medium is heated when the strips absorb solar radiation incident through the tiles, wherein in each course there is a space wherein
15 air is held over and along the strip in that course.

Those skilled in the science will appreciate that the invention provides the benefits of effective solar heating (including a thermally insulative air blanket) without requiring a separate flat plate collector or other complications of the prior art. It will also be appreciated that these
20 benefits may be extended over substantially all of the roof or wall face, potentially well beyond what is available from a conventional collector.

In each course the air may be held in said space by cooperation among the battens, the tiles and/or the strips.

The duct preferably extends through each said space. The strips
25 may be provided with means, such as brackets or turned-up edges, to

-5-

support the duct, and the duct may comprise a flexible pipe extending substantially continuously through all said spaces.

Rather than being a continuous length, it is preferred for convenience of laying the roof that each strip comprises transversely discrete sections. The battens may overlie the strips or the strips may overlie the battens.

The roof or wall face preferably includes ventilation means to ventilate each said space. The ventilation means may be formed in the strips, for instance by corrugating an edge whereby each strip is secured to a batten. The strips may also be formed and arranged to provide a run-off for moisture in said spaces.

The strips may be backed by a layer of thermally insulative material and the roof face may also include a semi-porous membrane backing the strips.

The roof or wall face is preferably disposed generally towards the Equator.

Other features of the invention will be apparent from the following description, which is made by way of example only and with reference to the accompanying schematic drawings in which –

Figure 1 is a perspective view of a house;

Figure 2 is a schematic view in side elevation of part of a roof face of the house of *Figure 1*, which roof face embodies the invention;

Figure 3 is a schematic plan view from above of strips comprising a first layer of the roof face of *Figure 1*; and

Figure 4 is a schematic side elevation showing another embodiment of the invention.

-6-

Referring first to *Figure 1*, the house shown therein has a roof face **110**. As will be described in more detail hereinafter, the roof face **110** is arranged as a solar thermal collector. The roof face **110** is chosen for this purpose because it is disposed generally towards the Equator (in contrast to the roof faces **112**, **114** and **116**) and because it is large (in comparison with the porch roof face **118**).

It may be noted that if the disposition of the house of *Figure 1* were (as viewed from above) turned through 90° clockwise, the roof face **114** would then face the Equator and could be used as a solar collector instead of the face **110**. However, in this disposition it would be better to use the wall face **120** because of its greater size. (The invention is applicable to wall faces as well as to roof faces).

Referring now to *Figure 2*, this shows that the roof face **110** comprises a thermally insulative layer **210** and a plurality of counter battens **212** secured over the layer **210**. The counter battens **212** extend up and down the roof and are evenly spaced apart to support a plurality of aluminium strips **214a**, **214b**, **214c** etc extending across the roof and mutually overlapping at their edges to form a substantially continuous inner layer. Battens **216a**, **216b** etc are secured to the roof structure on top of the overlapping edges of the aluminium strips **214a**, **214b**, **214c** etc which have a matt black coating and will be described in more detail hereinafter with reference to *Figure 3*. The battens **216a**, **216b** etc thus hold the strips **214a**, **214b**, **214c** etc in place and they also support an outer layer of tiles **218a**, **218b**, **218c** etc each made of polycarbonate and transparent to solar radiation.

-7-

Considering the tile **218b**, this has a tail (lower end) which extends over the head (upper end) of the downwardly adjacent tile **218c** to provide a runoff for precipitation. Similarly the head of the tile **218b** fits under the tail of the upwardly adjacent tile **218a**. There are also weather laps (not shown,
5 but of common form) whereby the tiles overlap one another from side to side. Thus the tiles are imbricated together so that the outer layer is substantially continuous. The head of the tile **218b** is formed with a flange **220** extending down to engage the batten **216a** whereby the tile **218b** is secured at its head. The tail of the tile **218b** is held by a roofing clip **222** of
10 common form gripping a weather lap of the tile **218b** in well known manner. The tail of the tile **218b** is also formed with a lip **224** for engaging the downwardly adjacent tile **218c**.

All the tiles of the roof are similar and similarly laid save where special arrangements are needed at the base and summit and the sides of
15 the roof. As those skilled in the science will appreciate, at the base of the roof the tails of the lowest course of tiles overlay a fascia board, at the summit the highest course of tiles is capped with a ridge tile, and the end tiles in each course are mortared or bonded in place, with a shaped filling piece if required.

As can be seen clearly from *Figure 2*, there are spaces **226** between
20 the inner and outer layers of the roof, bounded by the tiles and the metal strips. A copper pipe **228** for water (or another fluid heat transfer medium) of a solar heating system extends through the each space **226**. The pipe **228** is releasably clipped in the downward edge of the aluminium strip
25 **214a**, which is turned up at **230** to wrap around the pipe **228** in a thermally conductive connection therewith.

-8-

In use, when the sun shines on the roof face **110** of *Figure 1*, solar radiation passes through the transparent tiles **218a**, **218b**, **218c** etc and falls on the aluminium strips **214a**, **214b**, **214c** etc, which are highly absorbent to the incident radiation and thereby are strongly heated. The heat from the strip **214a** is passed by thermal conduction through the copper pipe **228** and thence into the water it contains, to be used for space heating or as hot water. The pipe **228** is laid sinuously across the roof (being formed to be flexible or having curved connectors at its ends) so that it passes repeatedly through the each space **226** between the first and second layers of the roof. In this way the temperature of the water is raised further.

It should also be noted that each space **226** is effectively enclosed. The flange **220** at the head of the tile **218b** cooperates with the batten **216a** to prevent any substantial upward convection of air from the space **226** and there is a similar arrangement at the tail of the tile **218b**. Thus air is held in the space **226** to provide a blanket against heat loss.

The space between the inner and outer layers of the roof face **110** may be ventilated to avoid the deleterious effects of dampness, especially as may arise from condensation, and means for this will now be described with reference to *Figure 3*.

As can be seen in the plan view of *Figure 3*, each of the aluminium strips **214a**, **214b** and **214c** (and other similar strips covering the roof) is made up of transversely discrete segments each some 2000 mm long by 500 mm wide. Each segment is longer than the width of the tiles, in the transverse direction. The strips all mutually overlap along their long edges, which extend transversely across the roof, and the width of the non-

-9-

overlapped portion of each segment is no greater than the depth of the tiles in the up-down direction. Along the length of each overlap the edge of the overlying strip is turned up to hold a pipe, as at **230** (*Figure 2*). Adjacent this edge each strip is formed with a corrugated section **240** providing channels running widthwise of the strip (ie down the slope of the pitch roof). These channels ventilate the space between the aluminium strips and the tiles which overlie them.

The channels also provide a means whereby any moisture, eg from condensation, may drain down through this space. To continue this drainage means downwards the turned up edges of the aluminium strips are perforated as indicated at **242**.

Finally with regard to drainage, any condensation on the underside of the tile **218b** will run down and drain out of the space by way of the lip **224**, which does not have sealing engagement with the downwardly adjacent tile **218c** or may be formed specifically to provide a drainage passage. This applies to each tile of the roof, of course.

As can also be seen in both *Figures 2* and *3*, the aluminium strips **214a**, **214b**, **214c** etc are each formed with rows of upstanding nubs **244** and **246** whereby the strips are mutually arranged during laying and the battens **216a**, **216b** etc positioned.

It will now be understood that the invention enables substantially all of the roof face **110** to serve as a solar collector with the benefits of effective insulation and ventilation.

Figure 4 shows a second embodiment of a pitched roof according to the invention, omitting the ties thereof for simplicity of illustration. This embodiment has two notable modifications compared with that of *Figure 2*.

-10-

First, each metal absorbent strip **410** is laid on top of a corresponding batten **412a**, rather than below it. (With an insulative layer **414** between the battens **412a** and **412b** as shown, the strip **410** may thus be substantially flat). Second, the pipe **416** for the solar heating system is held in brackets
5 **418** secured to each strip **410**. (A thermally conductive paste may be placed between the pipe and the brackets to improve heat transfer).

Various modifications may be made to the invention as described. For instance the aluminium strips may be replaced by strips of black synthetic plastics material absorbent to solar radiation, which reduces the
10 cost and may simplify laying but may have a performance penalty from the absence of conductive coupling to the pipe for the heat transfer fluid. The strips (whether of metal or plastics) may be formed to embody the duct. The tiles may be made of glass or some material other than polycarbonate and may be coloured or otherwise treated to modify the appearance of the roof
15 (provided, of course, that the tiling layer remains transparent to solar energy). The tiling layer may also be made to block any outward loss of heat, for instance by being formed with an inwardly reflective coating. The tiles may be formed, eg with fresnel prisms, to focus incident solar radiation on the pipe for the heating water. The battens may be made of wood, as is
20 conventional, or of any other suitable material. The battens may also embody the duct. Finally it will be understood that systems using the invention may be used for cooling as well as heating, by running the system at night.

-11-

Claims

1. A roof or wall face comprising a plurality of battens spaced apart to define a plurality of transverse courses, a plurality of tiles supported
5 by the battens in the courses defined thereby to provide an outer layer of said face, which tiles are transparent to solar radiation, a plurality of strips arranged one for each course to form an inner layer substantially coextensive with the outer layer, which strips are absorbent to solar radiation, and a duct for a fluid heat transfer medium of a solar heating
10 system extending lengthwise of the strips so that in use the fluid medium is heated when the strips absorb solar radiation incident through the tiles, wherein in each course there is a space wherein air is held over and along the strip in that course.
- 15 2. A roof or wall face as claimed in claim 1 wherein in each course air is held in each space by cooperation among the battens, the tiles and/or the strips.
- 20 3. A roof or wall face as claimed in claim 1 or claim 2 wherein said outer layer extends over substantially all of said face.
4. A roof or wall face as claimed in any preceding claim wherein the duct extends through each said space.
- 25 5. A roof or wall face as claimed in any preceding claim including means on the strips to support the duct.

-12-

6. A roof or wall face as claimed in claim 5 including brackets secured to the strips to support the duct.

5 7. A roof or wall face as claimed in claim 5 wherein edges of the strips are turned up to support the duct.

8. A roof or wall face as claimed in any preceding claim wherein the duct comprises a flexible pipe extending substantially continuously
10 through all said spaces.

9. A roof or wall face as claimed in any of claims 1 to 3 wherein the strips are formed to embody the duct.

15 10. A roof or wall face as claimed in any preceding claim wherein the strips each comprise transversely discrete sections.

11. A roof or wall face as claimed in claim 10 wherein, in each course, each section is of greater overall dimension than each tile in the
20 transverse direction.

12. A roof or wall face as claimed in any preceding claim wherein the strips mutually overlap along transverse edges and, in each course, the width of the non-overlapped portion is of no greater overall dimension than
25 each tile in a direction orthogonal to the transverse across said face.

-13-

13. A roof or wall face as claimed in any preceding claim wherein the battens overlie the strips.

5 14. A roof or wall face as claimed in any of claims 1 to 12 wherein the strips overlie the battens.

15. A roof or wall face as claimed in any preceding claim including ventilation means to ventilate each said space.

10

16. A roof or wall face as claimed in claim 15 wherein said strips are formed with said ventilation means.

17. A roof or wall face as claimed in claim 16 wherein each strip
15 has an edge whereby it is secured to a batten, which edge is corrugated to provide said ventilation means.

18. A roof or wall face as claimed in any preceding claim wherein the strips are formed and arranged to provide a run-off for moisture in said
20 spaces.

19. A roof or wall face as claimed in any preceding claim including a layer of thermally insulative material backing the strips.

25 20. A roof or wall face as claimed in any preceding claim including a semi-porous membrane backing the strips.

-14-

21. A roof or wall face as claimed in any preceding claim, which face is disposed generally towards the Equator.

5 22. A roof or wall face substantially as hereinbefore described with reference to and as shown in the accompanying drawings.
